1. Suggested Modifications

- Display thread changes after every insertion.
- Insert values smaller than the minimum and larger than the maximum.
- Verify predecessor and successor results after insertion.

2. Objectives

- **Dynamic Thread Visualization:** Track and display precise thread pointer shifts, tracking assignments, and lthread/rthread flag states in real-time as nodes are appended.
- **Extremal Boundary Integration:** Validate structural stability and boundary preservation during insertions that extend past the active minimum and maximum key thresholds.
- **Automated Neighbor Verification:** Programmatically cross-verify node neighborhoods using a continuous execution checker to prove that every thread perfectly matches its strategic inorder predecessor or successor.
- **Eliminate Traversal Overheads:** Maintain structural stackless efficiency to run sequential O(n) printing routes using clean thread links without runtime stack layers.
